How to Write an Abstract That Will Be Accepted for Presentation at a National Meeting

David J Pierson MD FAARC

Introduction

Preparation, submission, and presentation of an abstract are important stages in the life cycle of a research project. Though not all studies go through these stages, most do. There are a number of advantages to the abstract writing and presenting process, as opposed to simply preparing a manuscript and submitting it for publication once the study has been completed. By requiring the investigator/author to reduce the whole project into a brief synopsis, it forces concentration on the most important aspects of the study’s purpose, design, findings, and implications, and in so do-

Preparation, submission, and presentation of an abstract are important facets of the research process, which benefit the investigator/author in several ways. Writing an abstract consists primarily of answering the questions, “Why did you start?” “What did you do?” “What did you find?” and “What does it mean?” A few practical steps in preparing to write the abstract can facilitate the process. This article discusses those steps and offers suggestions for writing each of an abstract’s components (title, author list, introduction, methods, results, and conclusions); considers the advantages and disadvantages of incorporating a table or figure into the abstract; offers several general writing tips; and provides annotated examples of well-prepared abstracts: one from an original study, one from a method/device evaluation, and one from a case report. Key words: research, abstracts, writing, publications, research methodology, devices, equipment evaluation, case report, medical illustration, communication, conferences and congresses. Preparation, submission, and presentation of an abstract are important stages in the life cycle of a research project.

Preparation, submission, and presentation of an abstract are important stages in the life cycle of a research project.
ing clarifies the writer’s thinking about the project. It moves the project along the path to preparation of the full manuscript (something that intimidates many novice authors) by necessitating a concise synthesis of the data, and assembling the results for inclusion in a poster facilitates decision making on the best way to display and interpret the results. It subjects the author’s work to peer review, albeit in abbreviated form.

Pragmatically speaking, having an abstract on the program is the only way many investigators can obtain permission and/or institutional support for attending an important professional meeting. More importantly for the work itself, presentation of the findings at a national meeting of one’s peers gets the message out earlier than is generally possible with full peer-reviewed manuscript publication, thus speeding up the advance of knowledge and practice. And discussing the project and its findings with colleagues at the meeting nearly always yields insights, questions, and interpretations that alter and improve the final manuscript.

However, those benefits cannot be realized unless the abstract is correctly and expertly prepared—and accepted for presentation at the meeting. This article describes the components of an abstract, offers practical suggestions for optimizing the message and impact of each component, and provides general advice on abstract preparation and tips for increasing the likelihood that one’s abstract will be accepted. Although experienced abstract writers may find useful things in this article, it is aimed primarily at those who are preparing and submitting an abstract for the first time.

My focus in this article is on the Open Forum, the sessions for original research at the annual International Respiratory Congress of the American Association for Respiratory Care. However, much of what is in this article also applies to preparing abstracts for other scientific meetings. Most of the discussion is about abstracts reporting research studies, although equipment evaluations and case reports are also included, because the Open Forum accepts abstracts of those as well as of more traditional investigations.

What Is an Abstract?

An abstract is a condensed version of a full scientific paper. It describes a study and its results. It is a means of conveying to one’s peers what was done and why, what was found, and what the implications are. Because it is strictly limited, either in the number of words it can contain or in the space it can occupy on a page, an abstract can be only a “bare bones” version of all the information pertaining to the study. On the other hand, the selection committee must decide whether to accept the abstract, and meeting attendees will decide whether to come to the session at which it is presented, just on the basis of what it contains. There must therefore be enough “meat,” especially in the methods and results sections, to communicate the study’s essential message.

Scientific papers have abstracts that are similar to but not the same as abstracts for presentation at meetings. The format may be different, depending on the requirements of the society or the meeting. Meeting abstracts typically allow more liberal and extensive use of abbreviations than article abstracts, and they may contain references, tables, or figures. The abstracts of published articles are retrievable through electronic search engines such as PubMed. Although meeting abstracts are often published, either as supplements to or in regular issues of the host society’s journals, they are not indexed by the National Library of Medicine and usually cannot be found by searching on the Internet.

That an abstract was published in the proceedings of a professional society’s meeting does not signify that the society sanctions or otherwise endorses the research the abstract describes. Although many abstracts are published and can thus be cited as references in scientific papers, they are well below full peer-reviewed reports on the ladder of scientific value and should never be thought of as equivalent. They are not “publications” in the same sense as full reports, and they go in a separate section of the author’s curriculum vitae. Some scientific journals do not allow citation of abstracts in reports they publish, and most journals at least discourage reference to abstracts.

An abstract is only an intermediate stage in a yet unfinished project, completion of which requires publication of a full manuscript in a peer-reviewed journal. In fact, most presented abstracts actually never see full publication. A recent systematic review of 19,123 research abstracts, presented at 234 biomedical meetings between 1957 and 1998, found that only 45% were ultimately published as full papers. The proportion of Open Forum abstracts that are subsequently published has not been formally determined, but I think it is substantially lower than 45%. There are many possible reasons, but the most regrettable is when the investigator/author fails to write up and submit a full manuscript of a publishable study.

Preparation for Writing the Abstract

My mentor, Thomas L. Petty, once explained to me the relative difficulty of presenting complex information clearly and concisely. To paraphrase Dr. Petty’s advice, on being asked to give a talk on a particular topic, “If you want a 10-min summary, I can have it for you a week from today; if you want it to be 30 minutes, I can do it tomorrow; if you want a whole hour, I’m ready now.” Writing an abstract is in the first of those categories. There are few messages the gist of which cannot be distilled down to a
brief presentation, but to do so effectively requires clear thinking, careful planning, and concise, efficient communication.

Because putting together a good, professional looking abstract takes time, writing it should not be put off until the day before the final deadline for submission. This is especially important for first-time authors, who will benefit from discussing the project and from going over preliminary drafts with someone who has more experience. Enough time should be allowed for everyone listed as an author to have input into the abstract, and for each of them to sign off on the final version.

The purposes of a research abstract are to address in abbreviated form what should be communicated in a scientific paper:
- Why did you start?
- What did you do?
- What did you find?
- What does it mean?

The first of these questions applies to the introduction (or background), the second to the methods section, the third to the results, and the fourth to the conclusions. An abstract needs to contain concise but coherent answers to those questions, and nothing more.

Generally, a given study should be reported in a single abstract. There are legitimate exceptions, such as presenting the design and methods of a complex clinical study at one meeting and the findings at a subsequent meeting, or presenting 2 distinct aspects of the study (such as the overall initial results and then the complications or subsequent follow-up), especially if these are appropriate for different audiences. However, attempting to squeeze as many individual presentations as possible out of a single project, using the “LPU” (“least publishable unit”) approach, although all too prevalent, is the publishing equivalent of polluting the environment. Any short-term gain for the individual investigator is at the expense of the greater scientific community, for which coping with an ever-increasing volume of new data constitutes an obstacle to progress.

Previously presented abstracts should not be reread for submission to additional meetings. The same abstract can be presented at a local or regional meeting and then again at a national meeting, but not at more than one national meeting—even to different societies or audiences. Although a full paper may already have been submitted, the contents of the abstract should not have been published prior to its presentation at the meeting.

The first step in writing an abstract is to read the instructions. Professional societies nearly always provide guidelines and specifications for submitting abstracts to their meetings, and while certain things are common to all of them, there are important differences. Detailed, explicit instructions for preparing an abstract for the Open Forum are posted at Respiratory Care journal’s web site. For many meetings there is a form on which the abstract must be printed. Printing the finished abstract on this form is one of the very last steps in the process. One should make copies of the form for working drafts, and save the original for the “final final” version, after all the rewrites, copyedits, and corrections have been accomplished.

First-time abstract authors especially may find it useful to read through the published abstracts from the most recent annual meeting. This helps to illustrate the concepts discussed in this article and to develop a feel for what a good abstract looks like. In addition, although they differ in focus and target audience, several published guides to abstract preparation are available. For this article I have selected 3 abstracts from the 2003 Open Forum that I consider particularly good examples from the perspective of format and style. Figure 1 shows a representative abstract of an original research study. Figure 2 illustrates a methods-and-devices abstract. Figure 3 shows an abstract for a case report.

Title

The title should be an accurate promise of the abstract’s contents. It should convey as much as possible about the context and aims of the study. In addition, an abstract’s title is most effective when it refers to its overall “take home message.” Ideally about 10–12 words long, it should include the scope of the investigation, the study design, and the goal. In general it is preferable to make the title a description of what was investigated rather than to state the results or conclusions. Studies of published research papers whose titles were statements summarizing their results (“Recruitment Maneuvers Optimize Outcomes in ARDS”) have found that the great majority of them overstep the implications of their data and are technically incorrect.

The abstract’s title should be easy for readers everywhere to understand and should not include jargon or unfamiliar acronyms. Including key aspects of the study design is good (“A Survey of Department Managers’ Attitudes on...”), but nonspecific phrases such as “A Study of...” or “An Investigation Into...” are redundant and should be avoided. Plays on words and cute or deliberately provocative expressions catch the reader’s attention but tend not to wear well in the long run and may appear to trivialize the serious work being reported.

Authors and Affiliations

The list of authors should be restricted to those individuals who actually did the study—conceived it, designed it, gathered the data, crunched the numbers, and wrote the
ABSTRACT

Title is clear and explicit (although longer than the ideal).

All abstract components in a single paragraph.

Narrative results summarize (but do not duplicate) what is in the table.

Variables in the table include units.

Data presented as mean ± SD unless specified otherwise.

Using same font as in text makes tables easier to read.

Statistical results make clear what was compared.

Fig. 1. A well-prepared abstract reporting an original study,1 taken from the 2003 Open Forum.14 This abstract includes a table, which permits inclusion of more data than would be possible with text alone. Note that the table consists of actual (mean) data—not percentages or trends. The comments and arrows indicate noteworthy features and illustrate points made in the text.

Introduction or Background

This brief section answers the question, “Why did you start?” and should provide a context or explanation for doing the study. Space is at a premium, so a short sentence or two must suffice. This section should also state the aim of the study, and ideally should include a concise statement of the study’s hypothesis. A legitimate scientific study is not done to prove that something is true, but, rather, to find out whether it is true. The importance of that distinction may not be immediately apparent, but it actually makes a huge difference.18 Thus, the hypothesis may be either that device X is superior to other devices, or that it is no different, but the statement of a formal hypothesis reinforces the investigators’ objectivity and lack of personal investment in a particular outcome. It also focuses both the author and the reader on the abstract’s true message. Here are 2 examples of concisely stated but informative study hypotheses:

• “We hypothesized that the use of mask A (in comparison with mask B) would decrease the incidence of unsuccessful NPPV attempts.”

• “Our null hypothesis for this study was that pulmonary rehabilitation produces no change in psychological or...
Physiological aspects of quality of life, as measured by the SF-6.

**Methods**

The methods section of a research paper could well be written before the research itself is begun and any data collected, and the same is true for abstracts. This section answers the question, “What did you do?” This is the section of submitted manuscripts that is most often identified by reviewers and editors as deficient and the reason for rejection. In an abstract the description of the methods has to be concise, and many details of what was done must be omitted. However, in the space available the reader can be given a good idea of the design of the study, the context in which it was done, and the types of patients or measurements that were included. For a study involving patients or other human subjects, it should be explicitly stated whether the study was retrospective or prospective, and whether there was randomization. The source of the sample (eg, randomly selected, consecutive series, convenience sample) and the context in which the study was done should be specified.

**Results**

Here the abstract needs to tell the reader what the findings of the study were. Phrases such as “The findings will be presented” are unsatisfactory. Although space is limited, it is important to give the main results not just in subjective terms (“We found device X to be superior to device Y”) but also in the form of some real data. The results that pertain to the study’s hypothesis and that constitute the primary end points described in the methods, must be included—even if no statistically significant differences were found. Data from which the conclusions will be drawn should be reported in as much detail as space allows.

Sometimes a study is negative with respect to the primary outcome variable, although differences in one or more secondary or peripheral (or even unplanned) measurements may be statistically significant. The main hy-
pothesis should not be lost track of in such cases. It is
better to say that there was no difference in the primary
outcome of the study (noting any additional results,
significant or not, as space permits) than to refocus the study
toward the findings that were statistically significant.

If the study was designed so that a difference with \( p = 0.05 \)
would be considered significant, and the difference turns
out to be \( p = 0.09 \) or 0.15, that difference is not signifi-
cant—period. It is almost always a mistake to discuss
trends and “almost-significant differences.” According to
the power and sample size estimations that should be made
before the data collection begins, differences in the results
will be either significant or not significant.

Some Writing Tips

Use simple declarative sentences. Active voice is pref-
erable to passive voice: “We studied 15 patients with
ARDS.” is much better than “Fifteen patients with ARDS were studied.”

Use generic names for drugs and devices, unless the specific brand used is a key aspect of the study. For example, if the abstract reports an evaluation of a particular ventilator’s response time to patient inspiratory effort, the ventilator needs to be identified by name. But if the study was about some aspect of ventilation that is not specific to a certain ventilator model, such as the effects of positive end-expiratory pressure on arterial oxygenation, the name of the ventilator is irrelevant.

A few abbreviations are so familiar that they do not need to be spelled out in the abstract on first use, but there are not many of these. Examples in our field are COPD, PEEP, FEV₁, and PaCO₂. However, an abstract’s readers may have widely different backgrounds, and all but the most commonplace abbreviations or acronyms should be spelled out the first time they appear. There must also not be too many of them, or the abstract’s flow will be slowed and the reader will be bogged down in the communication, missing the intended message. Local expressions and jargon should be avoided, and one should be especially cautious about coining new abbreviations for expressions specific to the study being described.

The abstract-preparation instructions may specify which font to use and are usually clear about margins and minimum sizes. Use of a proportional font such as Arial or Times New Roman, as opposed to a mechanical or non-proportional font, will permit more words to be squeezed into the allotted space. However, it is important not to try to get around the rules by using a smaller font or decreasing the line spacing below single-spaced. These things show. The abstract should be prepared exactly as the instructions say.

**Important Things to Do Before Final Submission**

Despite good intentions, there is often a rush to complete and submit the abstract before the deadline passes. It is important to re-read the instructions before printing the final onto the submission form, and to make sure they have been followed to the letter. The goal should be not to have a single grammatical mistake, misspelled word, or typographical error. A frustrating reality of abstract submission is that, despite repeated proofreadings, errors often remain invisible to the author who has labored so long over it. It can be very helpful to have someone unconnected with the study read the abstract. Before the final draft is submitted, every listed author must read and approve the abstract.

**Summary**

Preparing an abstract for presentation at a scientific meeting is an integral part of the research process, and aids the completion of a project in several ways. Success in abstract writing comes from application of the same basic principles that promote success in research. Focusing on the primary issues of why the work was done, how it was carried out, what was found, and what the potential implications are, is the most important strategy for preparing the abstract. In the writing process, clear, direct communication, strict adherence to published specifications and format requirements, and careful proofreading will increase the likelihood of producing a high-quality abstract and of having it accepted for presentation.
