Abstract

Turbuhaler and Diskus are commonly-used dry powder inhaler devices for patients with respiratory disease. Their effectiveness is limited in part by the patient's ability to use them correctly. This has led to numerous studies being conducted over the last decade to assess the correct use of these devices by patients and health care professionals. These studies have generally used device-specific checklists to assess technique, this being the most feasible and accessible method for assessment. However, divergence between the checklists and scoring systems for the same device in different studies makes direct comparison of results difficult and at times inappropriate. Little evidence is available to assess the relative importance of different criteria; however, brief patient training based on specific inhaler technique checklists leads to significant improvement in asthma outcomes. This paper reviews common checklists and scoring systems used for Turbuhaler and Diskus, discusses the problem of heterogeneity between different checklists, and finally recommends suitable checklists and scoring systems for these devices, based on the literature and previous findings. Only when similar checklists are used across different research studies will accurate comparisons and meta-analysis be possible.
**Introduction**

Dry powder inhaler (DPI) devices have been developed over the last two decades for treatment of asthma and chronic obstructive pulmonary disease (COPD). These small portable devices contain micronised powdered medication, often with a carrier, with the particles dispersed during inhalation. These devices were developed for use in adults and older children, and have been shown to deliver drugs safely and effectively.\(^1\),\(^2\) Several types of DPIs are available, some as single dose, capsule based inhalers such as the Rotahaler, Aeroliser, or Handihaler. More commonly, DPIs are multi-dose inhalers, either reservoir type inhalers, such as the Turbuhaler (similar to Flexhaler), Clickhaler, Easyhaler and Novolizer, or based on pre-filled blisters, such as the Diskus (Accuhaler), or blister disks such as the Diskhaler.

The acceptance of DPIs has been driven in large part by the enormous success in recent years of combination treatment with a corticosteroid and a long-acting \(\beta_2\)-agonist.\(^3\) The combination of budesonide and formoterol fumarate in the Turbuhaler (TH) (AstraZeneca, Sweden) (Symbicort\(^\circledR\)), and fluticasone propionate and salmeterol xinafoate in the Diskus (DIS) (GlaxoSmithKline, UK) (Seretide\(^\circledR\)), reflects current treatment guidelines for moderate to severe asthma and COPD. These devices have been found to be the most efficient and commonly used of the DPI devices.\(^4\),\(^5\)

Many factors play a role in the overall performance of the TH\(^6\) (Figure 1) and DIS\(^7\) (Figure 2), from their pharmaceutical formulations, to their mechanical and aerodynamic properties, to the way they are used by people with airways disease. Correct device use is critical to the delivery of medication to the airways. Many studies have been conducted to
assess and improve the way people use the TH and the DIS. Some studies have used specific devices for assessing individual components of inhaler technique. For example, devices such as the Turbutest measure the patient’s inspiratory flow through a placebo TH.\textsuperscript{8,9} Portable devices for assessing some components of inhaler technique were recently reviewed.\textsuperscript{10} One example is the “Inhalation Manager" which measures inspiratory flow through inhalation devices - including a stylized dry powder inhaler - using a pneumotachometer; this system also predicts drug delivery mass and particle deposition based on \textit{in vitro} data.\textsuperscript{11} This instrument is proposed as a tool for assessing and training patients on correct inhaler technique and for identifying the most suitable inhaler for an individual patient,\textsuperscript{11} but it is not feasible on a wide scale and requires technical support. The Turbuhaler whistle (AstraZeneca International, London, UK) is a simple device that whistles if the patient inhales above 35L/sec.\textsuperscript{12}

However, by far the most common, feasible and accessible method of assessing inhaler technique is through the use of device-specific inhaler technique checklists. The validity of inhaler technique checklists was initially established by Appel,\textsuperscript{13} who showed that trained personnel were able to achieve a 98\% success rate in predicting the bronchodilator response for asthma patients using their reliever inhaler devices by observing their inhaler technique. More recently, inhaler technique checklists have been shown to be feasible tools for assessment of technique. The clinical utility of inhaler checklists has been confirmed by studies with dry powder inhalers\textsuperscript{14} and with pressurized metered dose inhalers\textsuperscript{15} which have shown that, when brief patient training was based on a standardised inhaler technique checklist, there were significant improvements in asthma outcomes. Hence, it can be concluded that assessment and correction of asthma patients'
inhaled technique against a checklist is a valid measurement of the effectiveness of the inhalation devices in terms of delivering improved clinical outcomes.

A systematic review of the effectiveness of different inhaler devices in asthma and COPD noted problems in comparisons between studies because of variation in the relevant inhaler technique checklists. The objective of the present review was therefore to describe and compare the inhaler technique checklists and scoring systems reported for TH and DIS, and to recommend uniform checklists and scoring systems for use in future studies and in clinical practice.

**Review of the literature**

**Search strategy**

The search strategy included PUBMED, EMBASE, and International Pharmacy Abstracts to 2012. Keywords used for the search included ‘Inhaler technique’, plus ‘checklists’, ‘Turbuhaler’, ‘Turbohaler’, ‘Accuhaler’, ‘Diskus’, or ‘incorrect use’. The titles and abstracts of all articles produced by this search were assessed for inclusion before retrieval of full articles. These articles were then subsequently reassessed for inclusion, and only those presenting checklists for the TH and/or DIS and meeting the inclusion criteria were included in the review. No blinding of authors’ names or institutions was done, and no scoring system for study quality was used. The inclusion criteria were: studies of TH or DIS usage, involving patients with asthma or COPD and/or health care professionals. Only publications in the English language were
Letters to editors, commentaries, cost-analyses and surveys were excluded. Instructions packaged with the inhaler devices themselves were also included.

**Published inhaler technique checklists and reporting systems**

Twenty six research articles were included in the analysis of inhaler technique checklists for the TH and DIS. Table 1 lists these checklists, together with the list of steps in the manufacturers’ instructions.

**Number and categorization of steps**

Table 1 includes 24 different checklists for the TH, and 16 for the DIS. It shows substantial variation between checklists in the number of steps listed, ranging from three to fourteen steps for TH and three to thirteen steps for DIS. Most checklists included removing the TH cap (19/24) or opening the DIS cover (14/16), and all checklists included steps for loading a dose and inhaling the dose. However, first exhaling away from the mouthpiece was listed in fewer than half of checklists for both devices. The speed of inhalation, most often described as needing to be strong and forceful, was not mentioned in 4/24 TH and 3/16 DIS checklists. Almost all checklists included holding the breath after inhalation (21/24 for TH, 13/16 for DIS). Some checklists also included an item for waiting a specified time between doses, and one, rinsing and spitting out after use of the inhaler.

Some checklists (ten for TH, six for DIS) further identified a subset of steps as being “essential” or “critical”; these are indicated with bold text in Table 1. The number of these essential steps varied, most commonly four for TH and three for DIS. For TH the essential steps were usually holding the device upright during loading, twisting the base
around and back to load a dose, exhaling away from the device, and inhaling strongly and forcefully, and for DIS, the most common essential steps were opening the mouthpiece, pushing the lever to load a dose, and inhaling. However, the essential items varied substantially between checklists. In most cases, the authors stated that the selection of an item as essential or critical was based on their evaluation that if this step was incorrectly performed, little or no medication would reach the lung.

Other authors classified some steps as “common problem steps”. van Beerendonk divided the checklist into skilled and non-skilled items, stating that non-skilled items such as exhaling to residual volume required only information, whereas skilled items such as inhaling forcefully and deeply also required physical training.

**Scoring and reporting systems for inhaler technique checklists**

As with checklist items, scoring systems varied greatly between publications. The most common approach was to give a score of one for each correctly/satisfactorily performed step and a score of zero for each skipped or incorrectly/unsatisfactorily performed step. Kesten *et al* graded pharmacists’ TH skills as good, fair, adequate or skipped, with a score of zero for skipped/not adequate and a score of 1 for good/fair. Ronmark *et al* allocated a score of 2 for correct, 1 for not completely correct, and 0 for incorrect.

Some checklists had a more complicated scoring system. Steier *et al* gave a total score of zero if “a step was left out that was necessary for successful inhalation (e.g., opening of the cap, loading) or if the patient exhaled into the device”, and “all other attempts were
rated from 1-9 points”. Sestini et al gave a score of 1 for each item of the checklist considered as “minor”, and a score of 3 for each one considered as “major”. 

For reporting a patient’s overall inhaler technique, most authors reported the inhaler technique score as the sum of the scores for each step, or as the proportion of checklist items that were performed correctly. More complicated systems were used by some authors. Ronmark et al assigned “overall correct use” of the device if no step was performed “incorrectly” (score 0) and if no more than two of four specific steps (steps 2, 3, 5, and 7 in Table 1) were “not completely correct” (score 1). Lenney et al provided 3 checklists for each device: the first (A, called “Optimal Technique”) included all steps required to use the device correctly; the second (B, called “Some Delivery”) included 2-3 common errors relevant to the device, and the third (C, called “Little or No Delivery”) included more substantial errors. Each patient’s technique was graded as A, B or C according to the checklist to which it best corresponded.

For summarising population results, the most common approaches were to report the average per-patient score and/or the proportion of patients who demonstrated all checklist steps correctly or who had any errors. van der Palen et al and Basheti et al also reported the proportion of patients with “correct essential technique” (all essential steps in Table 1 correct), and Melani et al reported the proportion of patients with any “critical errors”. Some authors also reported data for each individual checklist step, reporting the proportion of patients performing each step correctly or incorrectly.

Source of information for checklists
It was not always possible to determine the source of a published checklist (Table 1). Authors often stated that they had based their checklists on the manufacturers' leaflets,\(^2^3,2^5,2^7,3^5,3^6\) previously published checklists,\(^3^7,3^8\) national and international asthma foundation guidelines,\(^1^7,2^9\) and/or developed their own. Personal or expert opinion was often used to justify the checklist items; for example Nimmo et al stated that the TH checklist steps were those "identified as necessary for correct inhalation technique for the purpose of the study".\(^3^9\)

**SUMMARY**

The above body of literature demonstrates that there is no defined standard for assessment of inhaler technique with TH or DIS, with regard to the number and content of steps in the relevant checklists. Not all studies stated the source of their checklists, and even when the source of the checklists was stated, there were many different sources. Scoring systems used to present the results of the assessments were very different as well, making it unfeasible to compare the results in many cases. Therefore, while overall similar processes are described in each checklist, the range of content and format presents a challenge with regard to drawing comparisons between the checklists and validation of the individual steps.

A recent review has called for standardization of the way inhaler device studies are conducted and the way they are reported to physicians and health authorities.\(^4^0\) Considering the above findings, the most obvious questions at this stage would be: which checklists are most appropriate to be used for future studies assessing and/or educating patients on correct TH and/or DIS technique? Which steps should be weighed more, i.e.
which steps can be considered essential steps? How should inhaler technique data be scored and reported? To answer these questions, we examined evidence for the clinical importance of each of the steps commonly included in checklists for the TH and DIS.

**Evidence for inclusion of individual technique steps into device checklists**

Each checklist deals with three overall processes: preparation of the device/loading of the dose, delivery of the dose and preparation of the device for storage. Within these three overall processes, we identified published evidence that supports individual checklist steps. It is not possible to find evidence for some of the steps that are included in the manufacturers’ instructions for a particular device; these recommendations may have been developed in-house, with various options tested and some perhaps abandoned, and the evidence not necessarily available in the public domain.

**A. Preparation of the device**

Most checklists describe the preparation of the device to include i) removing the cover (TH) or opening the cover (DIS) and ii) loading a dose for delivery.

i) While there is no published evidence on the importance, necessity or impact of removing the cover (TH) or opening the cover (DIS), the design of the devices means that it would be physically impossible for any medication to be delivered if this step was not performed. This may seem so obvious as to be unnecessary to check, but a small proportion of patients fail to complete this step.41
Loading (or preparing) a dose for delivery is described for both TH and DIS. For the TH, (Figure 1) the medication powder is stored in bulk in a reservoir (“Storage unit for drug”), above a dose well (“Dosing unit”) and prior to drug administration a single dose of dry powder needs to be aliquotted (“loaded”).* This is achieved by holding the device upright and rotating the grip at the base of the TH in one direction and back again. While early TH instructions specified starting with an anti-clockwise rotation, the manufacturer later clarified that the direction of initial rotation was irrelevant provided the base was rotated in both directions and a click was heard. If the device is upright, the drug falls by gravity from the reservoir into the Dosing unit, and excess powder is scraped off to make the measured dose available.** This is an important step as without it, an appropriate dose of medication will not be available for delivery.

In contrast, the DIS contains a “Coiled strip” containing metered doses of dry powder (Figure 2). When the “Lever” is pulled to the right, the two foil strips are peeled apart, and the dose is aligned with and exposed to the mouthpiece. Without the lever being pulled across, it is physically impossible for any medication to be inhaled.

** B. Delivery of the dose

This process involves all of the breathing manoeuvres required to move the drug from the device and into the body. Typically, the checklists involve a description of i) how to exhale the air from the lungs (how much and where), ii) how to place the mouthpiece of the device into the mouth, iii) how to inhale the medication from the device, and iv) breath holding after inhalation.
i) **Exhaling air prior to inhalation** is a physiological process. While some checklists do not include this step on the basis that it does not affect clinical outcomes, other checklists specify “exhaling to residual volume”, based on clinical experience that this ensures that the patient can make a deep and forceful inhalation. For both TH and DIS, it is important to **exhale away from the mouthpiece** as there is evidence that exhalation into the device may reduce the dose delivered to the lung. Exhalation into or near the device compromises the integrity of the dry powder dose: for both the TH and the DIS, it can displace the already-loaded dose of powder and introduce moisture, potentially causing aggregation of dry powder particles.

ii) **Placing the mouthpiece between teeth and lips before inhalation** (TH and DIS) may also influence clinical outcomes. A tight seal between the lips and the mouthpiece avoids air leakage that would otherwise reduce the inspiratory flow rate; having the mouthpiece passing the lips and the teeth is important, otherwise a portion of the aerosol particles may deposit onto the teeth and tongue decreasing the amount of medication reaching the lung.

iii) **Inhaling forcefully and deeply** i.e. generating sufficient inspiratory flow, has been shown to be important for optimal drug delivery for TH and DIS, as it ensures de-aggregation of the metered dose and deep lung deposition. Inspiration should be forceful from the beginning of inhalation rather than increasing gradually. Failure to do so results in partial delivery of the medication to the lungs and increased drug deposition in the mouth and pharynx. Maintaining a forceful and deep inhalation from the start of the inhalation maneuver, and for as long as possible, can ensure that
most patients can use a DPI (TH and DIS) irrespective of the resistance of the device or their disease severity. However, while most patients can achieve the required flow rate, flow rate is more likely to be a problem for the TH than for the lower resistance DIS.

iv) Breath holding following inhalation (TH and DIS) is included in most of the published checklists and the Global Initiative for Asthma (GINA) web site checklists for both the TH and the DIS (www.ginasthma.com/inhalers/slide 11.html, Accessed April 19, 2012). This is one of the most discussed items about inhaler technique checklists.

While the manufacturer’s instructions for the TH do not include this step, many clinicians advise inclusion of a breath-hold for DPIs to avoid confusion with pressurized metered dose inhalers (pMDIs), for which a breath-hold is necessary. For pMDIs, the original suggestion of a 10-second breath-hold was based on lung deposition studies, but the general recommendation for clinical practice is that the breath should be held only as long as is comfortable. A 5-second breath-hold is a realistic target for most patients.

C. Preparation of the device for storage

Replacing the cap after use of a TH or closing the lid of the DIS are the final steps articulated in inhaler checklists. While this step is post drug delivery, it serves to keep the device clean, prevent foreign objects from entering the mouthpiece and minimize absorption of moisture from the ambient environment. Therefore these steps are important in maintaining the drug integrity for subsequent doses. For the TH, replacing the cap is included in the manufacturer’s instructions, but in fewer than half of published TH checklists.
Evidence for additional steps

There does not appear to be any published evidence to support a 30 second delay between doses, and it is not included in manufacturers’ instruction leaflets in countries such as Jordan, Canada, Australia, and the United States. This step would only be relevant to patients prescribed two or more inhalation doses on each occasion. Likewise, an instruction to rinse the mouth after taking a dose, while important for patients using inhaled corticosteroids to reduce the risk of oropharyngeal side-effects, is not relevant to those using TH or DIS for delivery of short- or long-acting β2-agonists.

Nevertheless, if the perspective of Appel et al,13 is adopted i.e. that the better the inhaler technique (the more correct steps performed) by the patient, the better the clinical response expected,14,32 these additional steps should be considered while delivering a complete TH and DIS technique education. Patients for whom a second dose or mouth rinsing is relevant may need to be asked about these steps, as they may not necessarily think to perform them when asked to demonstrate their technique.

Essential steps for TH and DIS

As previously mentioned, in some published checklists a series of steps have been identified as “essential”. Considering the evidence above, it becomes clear that, without the completion of certain steps, it is unlikely that any medication would be delivered to the airways. It is these steps that could be considered “essential”. They include: opening/removing the cover, loading the device,42 which in the case of the TH should be completed while holding the device upright29,43 and inhaling through the mouthpiece forcefully and deeply.50,55 Failure to perform these steps will result in no medication
being available either because of the physical barrier of the cap of lid or the unavailability of the drug; or the drug failing to be transported out of the inhaler.

From the literature, the published checklists for TH and DIS that best describe all of the steps recommended are those published by van der Palen et al\textsuperscript{29} and Basheti et al\textsuperscript{14} (Table 2).

**Reporting TH/DIS technique data**

In order to allow comparison of data from different studies, we recommend that inhaler technique data should be presented as

1) the proportion of patients with correct technique (all steps in the checklist correct)

2) the proportion of patients with correct essential technique (all essential steps identified in each checklist correct)

3) the mean of inhaler technique scores (±S.D.)

4) for more detailed studies, the proportion of patients with correct technique for each individual step in the technique checklist.

If all of these metrics were reported (or at least recommendations 1-3), appropriate comparison of populations would be possible in different locations and over time. In addition, effectiveness of interventions designed to improve inhaler technique and thus clinical outcomes could be established.

**Clinical impact of using inhaler technique checklists**

In the literature and in clinical practice, there is broad acceptance that poor inhaler technique is a substantial contributor to poor asthma control and to increased health care
costs. For pMDIs, Giraud et al showed a strong relationship between poor technique, assessed with a standardized checklist, and a composite asthma instability index. A subsequent study by the same authors showed that assessment and correction of inhaler technique using a standardized checklist led to a significant improvement in asthma control, particularly in patients whose inhaler technique was sub-optimal at the start. Although there have been many studies evaluating dry powder inhaler technique, a review by Lavorini et al found that few studies had documented the relationship between incorrect technique and clinical outcomes; however, there is no reason to suppose that this would be any different than for pMDIs. The concept of essential steps is supported by the finding of Melani et al that patients with one or more critical errors on the TH or DIS checklist had significantly worse asthma control, impaired quality of life, activity limitation and sleep disturbance. The strongest confirmation of the value of inhaler checklists comes from studies in which inhaler assessment and skills training was associated with significantly improved asthma outcomes. Again, there are few, but in young children, Goren et al showed that improved TH technique with a rudimentary child-specific checklist was associated with greater bronchodilator effect. In the 6-month study by Basheti et al, a brief pharmacy intervention, with assessment and correction of inhaler technique and checklist-based inhaler labels, led to significant improvement in asthma outcomes compared with a control group. In this study, changes in asthma control measures over time seemed to relate more to the proportion of patients with all steps correct than to average inhaler technique scores.

Considering the difference in steps between TH and DIS checklists, another important practical recommendation that this review can add is that, where possible, only one type
of inhaler device should be used per patient. Previous studies have shown that use of
different devices predisposes patients to inhaler misuse compared with using only one
type of inhaler.12,67,68 In addition, substituting a different DPI for that previously used by
the patient can cause confusion for the patient.69 Skilled health care professionals have an
essential role in evaluating patients’ inhalation technique and ensuring they are using the
inhalers properly.12,50,61 Avoiding multiple inhaler devices for a patient can also lead to
fewer steps to teach/learn and hence less confusion in demonstrating/performing the
individual steps per inhaler device for health care professionals and patients.

Conclusion

Inhaler technique checklists have been used in the majority of studies investigating the
inhaler technique performance of patients and of health care professionals such as
pharmacists. This literature review demonstrates considerable heterogeneity in inhaler
 technique checklists for the same dry powder devices in different studies, which makes
direct comparison of results difficult. This may cause confusion for both patients and
health care professionals, and ultimately contribute to poor technique. The issue of
inhaler technique checklist heterogeneity was first raised more than a decade ago,16 but
more work clearly needs to be done to ensure standardization of checklists for clinical
and research contexts.

Checklists are feasible for use in clinical research and clinical practice, with no
equipment costs, and with minimal time required. Unlike existing inhaler technique
assessment devices which are only able to check some components of inhaler use, use of
a checklist ensures that every step required for delivery of medication is assessed.
However, the differences between the various checklists and scoring systems in the literature make the direct comparison of results difficult and at times inappropriate. Hence, in this review we have recommended checklists and scoring systems for the most commonly used DPIs, TH and DIS, based on the literature and previous findings. If future studies in this area use common checklists and scoring systems, the problem of inhaler technique assessment heterogeneity between different studies will be resolved allowing for more accurate comparisons between the results.

From the literature, the published checklists for TH and DIS that best describe all of the steps recommended above are those published by van der Palen et al\textsuperscript{29} and Basheti et al.\textsuperscript{14} The validity of these checklists is supported by evidence for significant improvement in asthma outcomes when technique is assessed and improved.\textsuperscript{14} It is recommended that future studies use these checklists so direct comparison between studies can assess the efficacy of specific interventions.

| Gracia-Cardenas \(^{17}\) | 1- Unscrew and lift off the cover  
2- Holds the inhaler upright  
3- Twist the red grip fully to the right as far as it will go and twist it back again to the left. A ‘click’ will be heard  
4- Breathe out gently taking care not to breathe into the TH  
5- Place mouthpiece between teeth and lips  
6- Inhaler forcefully and deeply  
7- Remove inhaler from mouth, hold breath for 8 seconds, and exhale away from the mouthpiece  
8- If further doses are needed, wait 30 seconds, and repeat steps from 2 to 7  
9- Replace white cap  
10- Rinse mouth with water. Do not swallow | Spanish guide for asthma management guidelines |
|---|---|---|
| Epstein et al \(^{17}\) | 1-Removing the cover before the first puff  
2-Not shaking the inhaler  
3-Holding the inhaler upright for priming  
4-Turning the wheel correctly to the right  
5-Turning the wheel correctly to the left until there is a click.  
6-Breathing out  
7-Breathing away from the inhaler prior to inhalation  
8-Putting the mouthpiece between the lips | Manufacturer’s recommendation and previous published studies by Hanania et al \(^ {18}\) and Kesten et al \(^ {19}\) |
| Hanania et al \(^{18}\) | 1-Remove cover  
2-Hold inhaler upright  
3-Turn bottom clockwise then anticlockwise  
4-Exhale away from inhaler to functional residual capacity or residual volume  
5-Insert mouthpiece between lips  
6- Breathe in forcefully and deeply  
7- Don't exhale, remove inhaler from mouth  
8-Hold breath to comfort (5-10 seconds)  
9-Exhale, wait 20-30 seconds before a second inhalation  
10-Hold upright  
11-Rotate bottom again before a second inhalation | Not stated  
(justifications given) |
| Kamps et al \(^{71}\) | 1-Rotate TH counter-clockwise and back while keeping it upright  
2-Place mouthpiece between teeth and lips  
3-Inhale forcefully and deeply | Netherlands Asthma Foundation  
1-Open DIS and push back handle completely  
2-Place mouthpiece between teeth and lips  
3-Inhale forcefully and deeply |
| Khassawnehet et al \(^{72}\) | 1-Unscrew and lift off the cover  
2-Hold the inhaler upright with the grip downwards  
3-Turn the grip until it clicks  
4-Breathe in rapidly and deeply | Checklist was derived from medication leaflet and previous studies \(^{36,28,73}\)  
1-Open the device  
2-Slide the lever until it clicks  
3-Breathe in rapidly and deeply |
| Kesten et al | 1-Remove the cover  
2-Hold inhaler upright  
3-Turn bottom completely to the right then left until click  
4-Exhale away from inhaler to functional residual capacity or residual volume  
5-Put mouthpiece between lips  
6- Breathe in forcefully and deeply  
7-Don't exhale, remove inhaler from mouth  
8-Hold breath according to comfort  
9-Exhale, wait a minimum of 20-30 seconds before second inhalation  
10-Hold upright  
11-Rotate bottom correctly | Not stated (justifications given) |
| Lareau et al | **Steps to prepare for inhalation after unscrewing/removing/opening the cap**  
Twist grip as far as possible in one direction  
Twist grip back until it clicks  
**Other steps given as critical errors:**  
- Failure to remove cap  
- Holding inhaler upside down  
- Failure to load dose  
- Blowing into device  
- Failure to make tight seal with lips  
- Inhalation too weak or too slow | Checklist was derived from instructions in the package inserts, and adapted from previous work |
